TITLE: Combined action of irradiation and a surface-active medium on the mechanical properties of zinc single crystals

SOURCE: Zhurnal prikladnoy khimii, v. 39, no. 10, 1966, 2184-2189

TOPIC TAGS: zinc, ~~zinc~~ single crystal, mercury coated crystal, crystal irradiation, proton irradiation, electron irradiation, gamma irradiation, alpha irradiation, beta irradiation, crystal mechanical property, irradiation effect, METAL FILM, TENSILE STRENGTH, DUCTILITYABSTRACT: Specimens of zinc single crystals, 10 mm long and 1 mm in diameter, coated with about 5μ mercury film were irradiated with protons, electrons, gamma-ray at an intensity of $4 \cdot 10^4$ g-equiv, beta-radiation with an intensity of 100 and 200 cm, or alpha-radiation with an intensity of about 2 μ cm, and then tested for tensile strength at a deformation rate of 6.5—10%/min. Another series of tests was made during irradiation of the specimens without previous irradiation. The test results showed that proton, electron and gamma irradiation during deformation of zinc single crystals coated with a thin film of surface-active material (mercury) appreciably increased the adsorption effect of the decrease in the strength and ductility of zinc caused by the presence of mercury. The additional decrease in the

Card 1/2

ACC NR: AP6034024

strength resulting from the combined action of the surface-active medium and irradiation varied from 25 to 40%, depending on the type and parameters of the irradiation source. Prolonged alpha, beta and gamma ray irradiation, as well as neutron and proton bombardment (1000 hr or longer), sharply reduced the strength of mercury-coated zinc single crystals, e.g., from 200 to 25-30 g/mm². The strength of mercury-coated zinc single crystals can slightly increase under the action of brief (20-25 hr) irradiation. This is associated with ordinary irradiation strengthening and also with facilitating the process of volume alloying due to the increased number of irradiation-induced point defects of the structure. The irradiation-induced increase of the adsorption effect (a strength decrease) is associated mainly with an increased mobility of the particles of the melt in the radiation field, with increasing defects in the base metal, and with ionization processes during irradiation. TITLE: Effect of a irradiation on the microplasticity of quartz glass

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 3, no. 1, 1967, 200-202

TOPIC TAGS: alpha radiation, glass, irradiation effect, plasticity

ABSTRACT: The effect of a irradiation with Pu^{239} (particle energy 5.14 MeV) on the microplasticity of quartz glasses was studied by means of microhardness measurements in which the length of the diagonal in indentations made with a diamond pyramid was determined. Both the indenter and the α particles penetrated the glasses to approximately the same depth (10-12 μ). Gauss distribution curves of the microhardness values for deformation of the glass with and without irradiation showed that the field of external α radiation causes a decrease in microhardness or increase in the microplasticity of quartz glass. The number of atoms displaced under the influence of the α bombardment was calculated to be approximately 2.76×10^9 atoms/cm³ sec. From the thermodynamic standpoint, the irradiation affects the strength of the glass by changing the free surface energy of the glass. Orig. art. has: 1 figura and 1 table.

AUTHOR: Troitskiy, O.A.; Terekhova, N.B.

TITLE: Mechanical strength of a pyroceramic in relation to the conditions of its preparation, state of the surface, and moisture content

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 1, no. 6, 1965, 984-990

TOPIC TAGS: pyroceramic, lithium aluminosilicate glass, pyroceramic preparation, glass mechanical property

ABSTRACT: The article deals with the relationship between the conditions of formation of pyroceramics of the lithium aluminosilicate system during the generation of crystallization centers, their structure, and their properties in samples with various surface states. The samples were subjected to preliminary heat treatments lasting various periods of time at 650C to allow the centers to form, and to the main heat treatment at 780C to cause the crystals to grow. The mechanical strength and microhardness were then measured. Electron microscopy was used to determine the degree of crystallization, and infrared spectra were taken at 2-5 μ to determine the moisture content qualitatively. Some of the

Card 1/2

L 3660-66

ACCESSION NR: AP5018936

3

samples were etched with 20% hydrofluoric acid (a 100-200 μ layer was thus removed). It was found that such chemical etching strengthens pyroceramics of the lithium aluminosilicate system catalyzed with titanium dioxide by a factor greater than 2. The microhardness of the pyroceramics was higher than that of the original glass, but the data showed a considerable scatter. The density of the pyroceramic increased with the duration of the pretreatment. The moisture content of the pyroceramic increased with the duration of the pretreatment. The moisture content of the pyroceramics was found to be greater than that of the original glass; the cause of this effect was not determined. Orig. art. has: 4 figures.

Planirovaniye sebestoimosti na mashinostroitel'nom zavode; metodika i praktika (Planning of Costs in a Machine-Manufacturing Plant; Method and Practice) Moscow, Mashgiz, 1959. 249 p. Errata slip inserted. 5,000 copies printed.

Reviewers: Z.N. Neyman, Engineer and Ye. P. Frolov, Engineer: Ed.: M.N. Boginskiy Engineer, Economist; Ed. of Publishing House: A.I. Tkachun; Tech. Ed.: V.D. El'kind; Managing Ed. for Literature on the Economics and Organization of Production (Mashgiz) T.D. Saksaganskiy

PURPOSE: This manual is intended for planning personnel and economists of machinery-manufacturing plants. It may also be useful to workers in other plants and economic councils as well as teaching personnel in economic vuzes and tekhnikums.

Card 1/4

Planning of Costs in a Machine-Manufacturing (Cont.)

SOV/1989

COVERAGE: The manual outlines the procedure for setting up a plan based on the cost of production in a machinery-manufacturing plant. This outline includes numerical examples which demonstrate the methods employed in relating various indices used in cost planning and points out the relationship between the cost and other aspects of the technical, industrial, and financial plan. Examples are also given for calculating the effectiveness of organizational and technical measures and planned savings for separate items in cost accounting. A balance method of calculating the plant cost of production plan covering everything from auxiliary shop outlays to the cost of gross production is included. No personalities are mentioned. There are no references.

1792. (591) CERTAIN CHARACTERISTICS OF SKIN PLASTY IN BURNS (Russian text) - Troitsky R. A. - KHIRURGIYA 1958, 5 (105-108)
Although autoplasty is the most reliable method, it cannot be used in all cases. Poor general condition of the patient and extensive and deep burns are conditions in which autoplasty is contraindicated. In small children homoplastic skin grafts are taken from their mothers. In adults the burned wounds should be covered with large flaps of skin taken from cadavers. This skin must be preserved at a temperature of +4°C for 1-2 days. The flaps should be applied tightly to the burned surfaces and sutured to the healthy skin. At the end of the first month the cadaveric skin is detached, but the granulations are smooth, healthy and suitable for auto-transplantation. Cadaveric skin is used in early and late secondary plasty in 2 patients and improvement of the general condition of the patient and the growth of healthy granulations were obtained. Late autoplasty was applied and the patients were able to resume their ordinary avocations. Primary skin autoplasty in burns of the fingers of the 3rd and 4th degree was used and excellent results were obtained.

TITLE: State of health of personnel servicing high, ultrahigh, and superhigh frequency generators at physical therapy units

SOURCE: Kazanskiy meditsinskiy zhurnal, no. 2, 1966, 82-84

TOPIC TAGS: radiation biologic effect, physiologic parameter, blood, cholinesterase, psychoneurotic disorder

ABSTRACT: The state of health of 84 nurses employed at physical therapy units in which they were exposed to radiation from high, ultrahigh, and superhigh frequency generators at electric field strengths ranging from tens to hundreds of v/m was investigated. The nurses complained of headaches, irritability, pains in the cardiac region, increased tendency to perspire, general debility, and restless sleep - less frequently vertigo, loss of hair, numbness of fingers, and epiphora. No pathological changes in internal organs were found. Vegetative vascular disturbances, a tendency towards anemia, leukopenia, thrombocytopenia, and an increased reaction of erythrocyte precipitation were found to be present. A decrease in the albumin-albumin level, an increase in the globulin content, and a decrease in the albumin-

globulin index were also established. Twenty-five of the nurses exhibited a tendency towards a reduction of the cholinesterase level in the plasma and erythrocytes. To protect medical personnel from electromagnetic radiation, improved screening by means of cotton fabrics containing conducting wire or by means of metallic netting can be applied, by systems for remote control of the equipment should be developed. ORG: Institute of Industrial Hygiene and Occupational Diseases, Gor'kiy (Institut gigiyeny truda i profbolemyey)		
TITLE: General health of persons working with HF, VHF, and UHF generators in physiotherapy machines		
SOURCE: Kazanskiy meditsinskiy zhurnal, no. 2, 1966, 82-84		
PC TAGS: microwave, VHF, human physiology, industrial hygiene, central nervous system, hematology		
ABSTRACT: A study was made of the effects of chronic exposure to <u>microwave</u> ²⁵ irradiation on medical personnel working with physiotherapy machines. The 80 machines studied had 12 different types of generators with working frequencies from 1.6 to 2450 Mc ($\lambda = 184 \text{ m} - 12.2 \text{ cm}$) and power of 20—350 w. Control panel working conditions for various types of generators and treatment setups are evaluated in terms of industrial norms. Physiotherapy working conditions exceed permissible industrial exposure limits (20 v/m or $10 \mu\text{w/cm}^2$) in almost every case, sometimes by as much as one to two orders of magnitude ($170 - 1000 \mu\text{w/cm}^2$). An experimental group of 84 physiotherapy nurses, and a control group of 27 nurses not exposed to electromagnetic fields, were kept under clinical observation for up to two years. The

L 27737-66

ACC NM AP601723

majority were from 30 to 50 years old and had been working more than five years. The principal complaints were of headache, irritability, chest pain, increased tendency to perspire, general debility, and restless sleep. Less frequent complaints included vertigo, falling hair, numbness of the fingers, and a tendency to weep. No internal pathologies or organic CNS changes attributable to work with microwaves were discovered. However, marked dermographism, acrocyanosis, and tremor of the outstretched arm were noted. The clinostatic reflex was sharply positive. The functional state of the olfactory and visual analyzers was tested. Light sensitivity and dark adaptation were impaired and the olfactory threshold was raised, indicating reduced excitability of these CNS centers. Capillaroscopy revealed dilation of venous branches with slowed blood flow in 10 subjects. Hypotonia was noted in 18 subjects. Arterial pressure asymmetries and lowered oscillographic indices were noted in 35 and 40 subjects. In 19 subjects, arterial pressure after physical stress fell off. These results indicate serious vascular dystonia in the experimental group. EKG studies of 72 subjects revealed sinus bradycardia and arrhythmia in 20 subjects. The average erythrocyte count was down in the experimental group. Erythrocyte sedimentation was faster in more than half the experimental group, the average being almost twice the normal rate. The average reticulocyte count was at the lower limit of the normal range. Erythrocyte diameter was decreased. Erythrocyte life appeared normal. Leukocyte, neutrophil, and especially lymphocyte counts were depressed in many subjects. Eosinophils were absent in 20% of the experimental group. The monocyte picture remained normal. The blood studies as a whole indicate a hyporegenerative hematopoietic reaction. In 35 subjects reexamined a year later,

Card 2/3

L 27737-66

ACC NR: AP6017293

erythrocyte and monocyte counts were down while other indices remained unchanged. In 83% of the experimental group, albumen was lower, (gamma-) globulin was higher, and the albumen-globulin coefficient was lower than in the control group. Decreased blood cholinesterase activity was noted in 25 subjects. Vegetative-vascular disturbances, accompanied by a tendency to anemia, leukopenia, thrombocytopenia, and increased erythrocyte sedimentation rates were found. It is concluded that chronic exposure to electromagnetic fields of the order of tens or hundreds of volts per meter in the VHF range can affect the general health of a person so exposed. TITLE: The Moon reveals itself [Radio astronomy^{2,55} used to study the moon]
^{12,55} (2+1)

SOURCE: Krasnaya zvezda, no. 4, 1966, 4

TOPIC TAGS: radio astronomy, lunar surface, lunar radiation, lunar temperature,
lunar topography, *lunar radio emission*

ABSTRACT: In an interview given a reporter of the Soviet armed forces newspaper Krasnaya Zvezda,* Professor Vsevolod S. Troitskiy of the Scientific Research Institute of Radiophysics of the Gor'kiy University im. N. I. Lobachevskiy elaborated on the contribution of radio astronomy to our understanding of conditions on the Moon. Recent measurements indicate that the temperature of the Moon increases to a depth of about 6 m and then the rise drops rather abruptly. The thermal conductivity of the Moon's upper layer was found to be 100 to 300 times lower than that of common terrestrial rocks. At a depth of 150—200 km, the lunar interior apparently attains a temperature of 1000 degrees. Troitskiy and his colleagues believe that lunar matter most closely resembles volcanic ash,

Card 1/3

L 15643-66

ACC NR: AN6003130

tuff, basalt, and other rock of so-called average basicity, and that the upper layer of the entire lunar surface is highly porous. By the use of a radio telescope, it was determined that the electric conductivity of the upper 3- to 4-cm layer of the lunar surface is 1 1/2 times greater than that of the rock located deeper. The electric conductivity of the upper layer of the Moon is equivalent to that of meteoric stone. The density of lunar matter increases 1.5 to 2 times from the surface to a depth of 3—4 cm. Apparently a 6- to 8-meter layer of porous matter covers the Moon's hard rock matter. If, however, according to computer data, density at a depth of 3 to 4 cm approaches 1, then the surface layer of the Moon has a density equal to only half the density of water. The depth of penetration of radio waves into the lunar rocks provides a source of information about their chemical and mineralogical composition. The depth of wave penetration for various terrestrial rocks was investigated and compared with that obtained for the Moon; it was found that lunar matter called "lunite," probably consists of 60—65% silicon oxide, 15—20% aluminum oxide, and 20% potassium, sodium, magnesium, and ferric oxides. Estimates were derived of the interior temperature distribution of the Moon on the basis of fissionable heating processes and it was postulated that the Moon has a hard core and that the concentration of radioactive elements is 5—6 times greater than on the Earth. For the past 3—4 years astronomers of the Gorkiy Institute have studied the radio emission of the Moon on 20 different wavelengths, ranging from 0.1 to 70 cm.

Card 2/3

L 15648-66

ACC NR: AN6003130

Some 30,000 measurements were carried out. Radio astronomers will continue to explore the Moon, concentrating their efforts first on learning the physical properties of the major features of the lunar relief; later, when large radio telescopes become operable, they will study the smaller features of the lunar surface. It is not excluded, the author concludes, that this problem will be solved sooner by those who land on the Moon. The landing of a space expedition on the Moon is now only an engineering problem.
